⌚ Time steps

$$\hat{y}_t = f(x_t)$$

⟳ Neuron with Recurrence

Recurrent Neural Networks (RNNs)

Recurrent Neural Networks

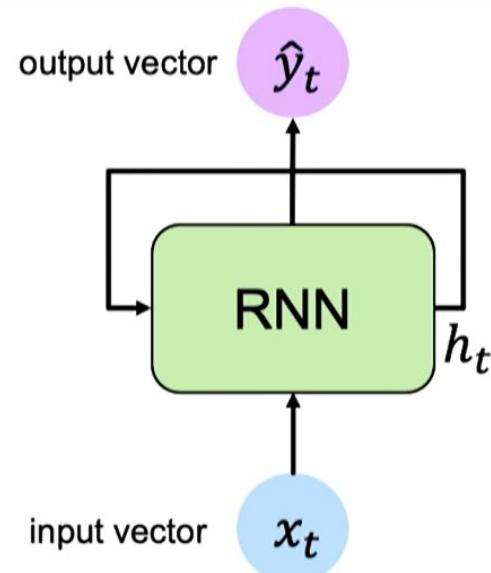

$$h_t = f_W(x_t, h_{t-1})$$

cell state function with weights W
 input old state

RNNs have a state h_t that is updated at each time step as a sequence is processed.

RNN Intuition

```
my_rnn = RNN()  
hidden_state = [0, 0, 0, 0]  
  
sentence = ["I", "love", "recurrent", "neural"]  
  
for word in sentence:  
    prediction, hidden_state = my_rnn(word, hidden_state)  
  
next_word_prediction = prediction  
# >>> "networks!"
```

Perplexity measures language model quality

- "It's raining outside"
- "It's raining bananas"
- "It's raining piouw;kcj pwepoiut"

- Inverse of the geometric mean of the number of actual choices we have when deciding which token to choose next.
 - Best case, the model always perfectly estimates the probability of the target token as 1.
 - Worst case, the model always predicts the probability of the target token as 0. In this situation, the perplexity is positive infinity.
- If the model predicts a uniform distribution over all available tokens in the vocabulary, the perplexity is equal to the number of unique tokens in the vocabulary.

$$\exp \left(-\frac{1}{n} \sum_{t=1}^n \log P(x_t \mid x_{t-1}, \dots, x_1) \right)$$

Output Vector

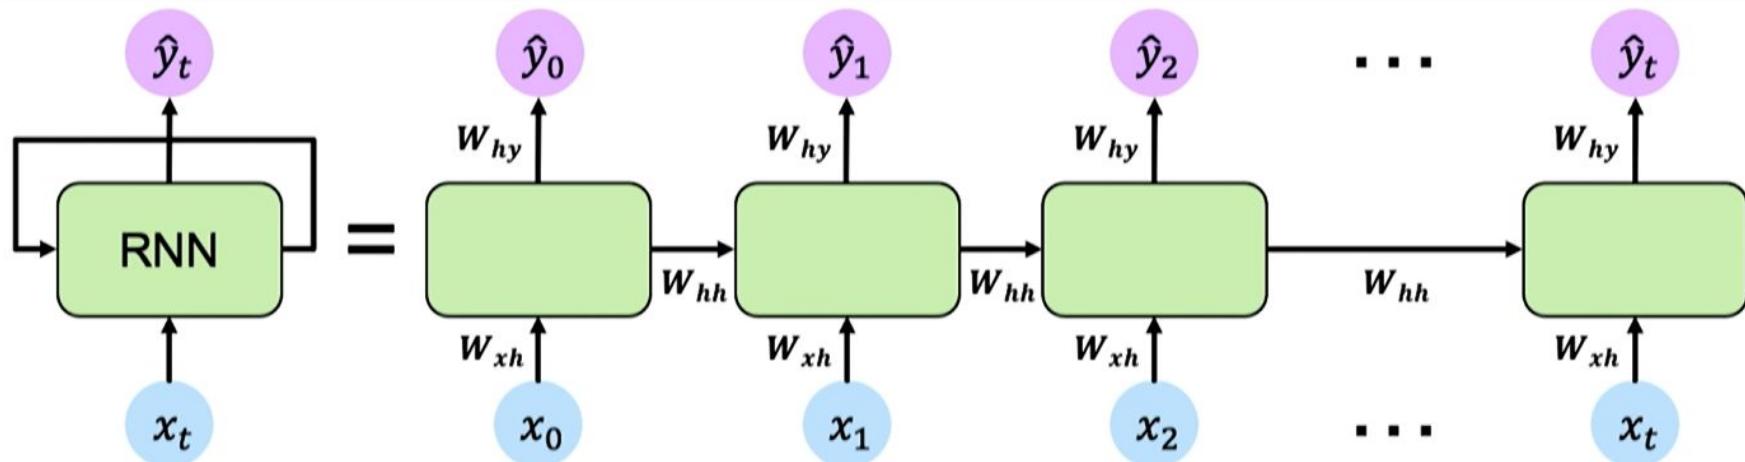

$$\hat{y}_t = \mathbf{W}_{hy}^T h_t$$

Short distance

One mole of carbon dioxide

Long distance

Harry Potter was a highly unusual boy in many ways. For one thing, he hated the summer holidays more than any other time of year. For another, he really wanted to do his homework but was forced to do it in secret, in the dead of night. And he also happened to be a wizard.

It was nearly midnight, and he was lying on his stomach in bed, the blankets drawn right over his head like a tent, a flashlight in one hand and a large leather-bound book (*A History of Magic* by Bathilda Bagshot) propped open against the pillow. Harry shoved the tip of his eagle-feather quill down the page, frowning as he looked for something that would help him write his essay, "Witch Burning in the Fourteenth Century Was Completely Pointless discuss."

The quill paused at the top of a likely-looking paragraph. Harry pushed his round glasses up the bridge of his nose, moved his flashlight closer to the book, and read:

Non-magic people (more commonly known as Muggles) were particularly afraid of magic in medieval times, but not very good at recognizing it. On the rare occasion that they did catch a real witch or wizard, burning had no effect whatsoever. The witch or wizard would perform a basic Flame Freezing Charmer and then pretend to shriek with pain while enjoying a gentle, tickling sensation. Indeed, Wendelin the Weird enjoyed being burned so much that she allowed herself to be caught no less than fortyseven times in various disguises.

Harry put his quill between his teeth and reached underneath his pillow for his ink bottle and a roll of parchment. Slowly and very carefully he unscrewed the ink bottle, dipped his quill into it, and began to write, pausing every now and then to listen, because if any of the Dursleys heard the scratching of his quill on their way to the bathroom, he'd probably find himself locked in the cupboard under the stairs for the rest of the summer.

The Dursley family of number four, Privet Drive, was the reason that Harry never enjoyed his summer holidays. Uncle Vernon, Aunt Petunia, and their son, Dudley, were Harry's only living relatives. They were Muggles, and they had a very medieval attitude toward magic. Harry's dead parents, who had been a witch and a wizard themselves, were never mentioned under the Dursleys' roof for years. Aunt Petunia and Uncle Vernon had hoped that if they kept Harry as bewitched as possible, they would be able to squash the magic out of him. And, to their fury, they had been unsuccessful. These days they lived in terror of anyone finding out that Harry had spent most of the last two years at Hogwarts School of Witchcraft and Wizardry. The most they could do, however, was to lock away Harry's spellbooks, wand, cauldron, and broomstick at the start of the summer break, and forbid him to talk to the neighbors.

Capture differences in Sequence Order.

Backpropagation Through Time

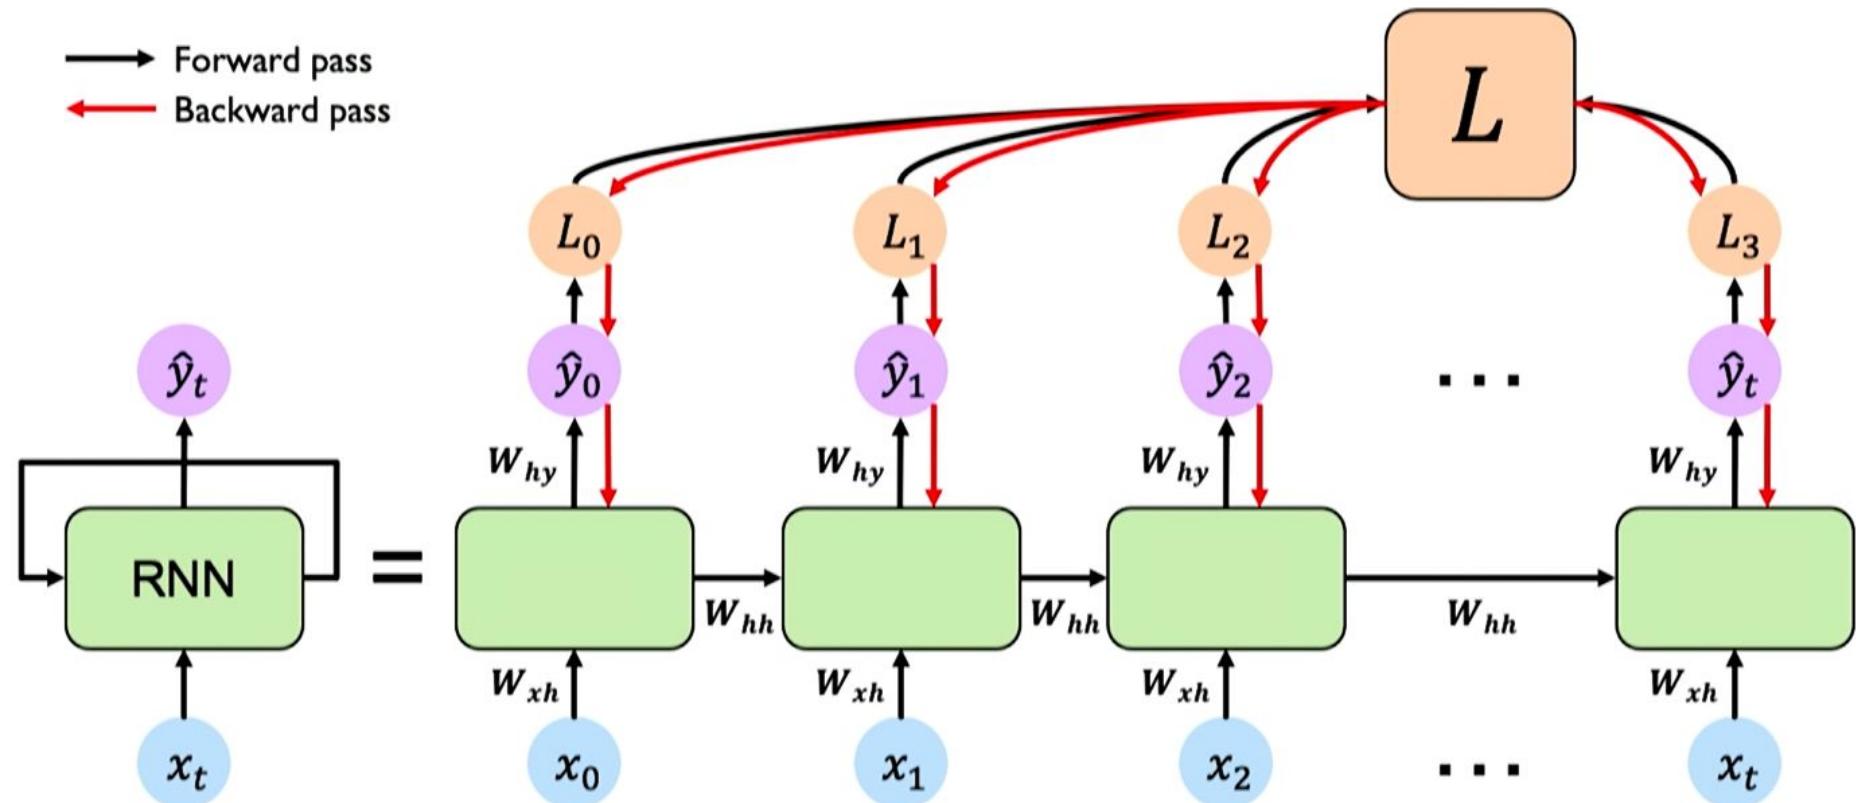

Backpropagation Through Time

→ Forward pass

Backpropagation Through Time

→ Forward pass
← Backward pass

Exploding and Vanishing

Many values > 1 :
exploding gradients

Gradient clipping to
scale big gradients

Many values < 1 :
vanishing gradients

1. Activation function
2. Weight initialization
3. Network architecture

Why are vanishing gradients a problem?

Multiply many **small numbers** together

Errors due to further back time steps
have smaller and smaller gradients

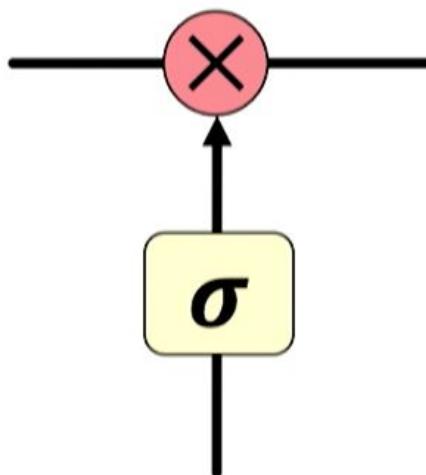

Bias parameters to capture short-term
dependencies

Idea: use **gates** to selectively **add** or **remove** information within **each recurrent unit with**

Pointwise multiplication

Sigmoid neural net layer

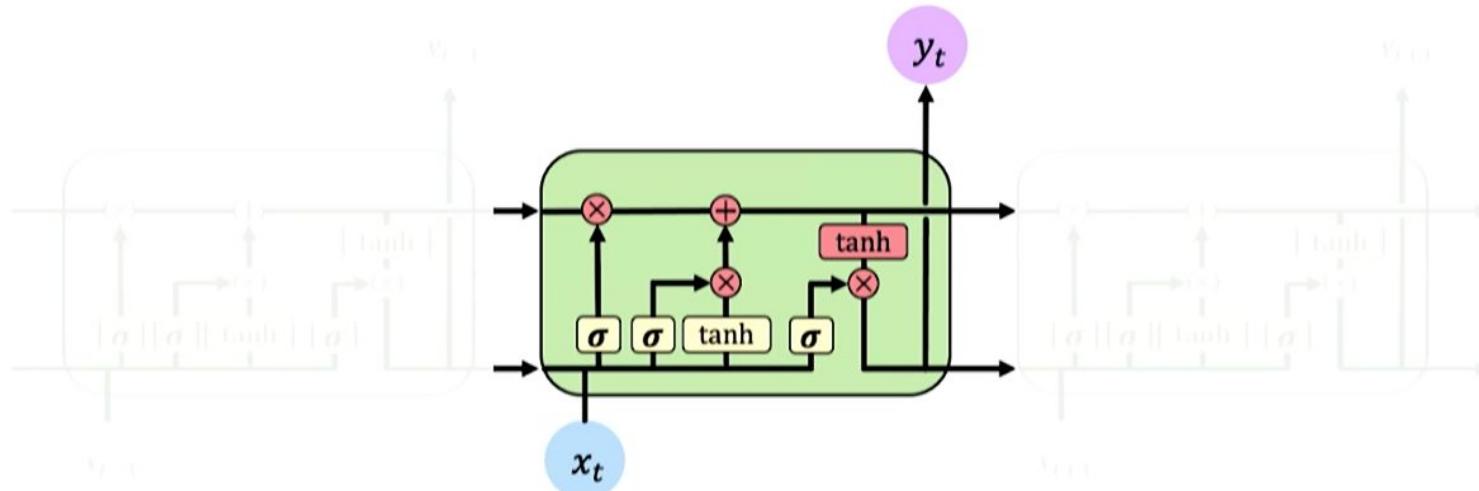

gated cell
LSTM, GRU, etc.

Gates optionally let information through the cell

Gated LSTM cells **control information flow**:

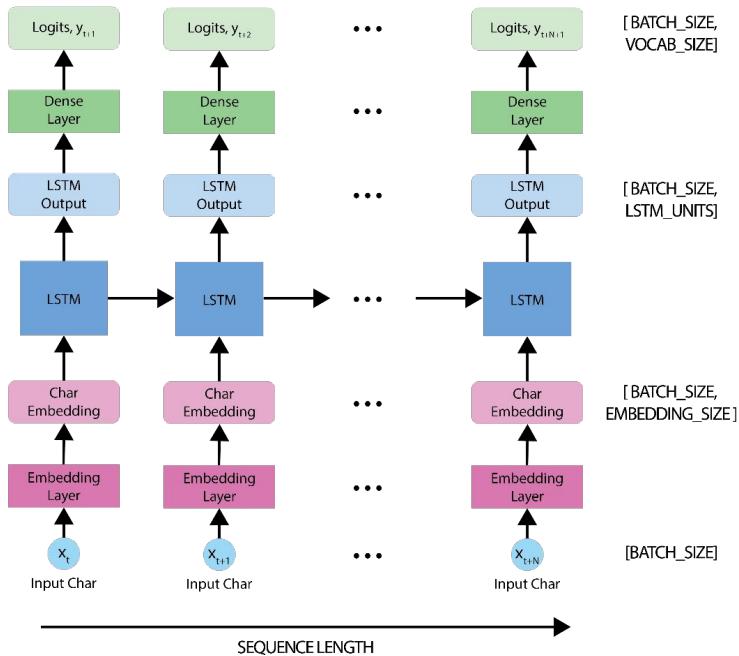

- 1) Forget
- 2) Store
- 3) Update
- 4) Output

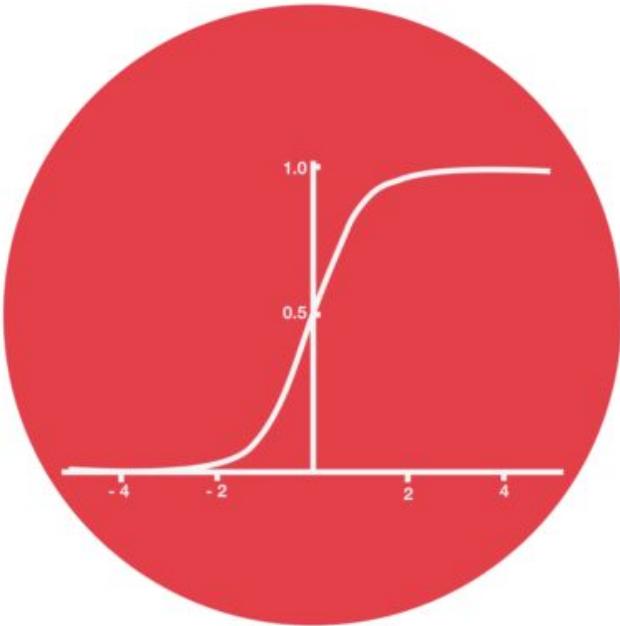

LSTM cells are able to track information throughout many timesteps

```
 tf.keras.layers.LSTM(num_units)
```

1. Maintain a cell state
2. Use gates to control the flow of information
 - o Forget gate gets rid of irrelevant information
 - o Store relevant information from current state
 - o Selectively Update cell state
 - o Output gate return a filtered version of the cell state
3. Backpropagation through time with partially uninterrupted gradient flow

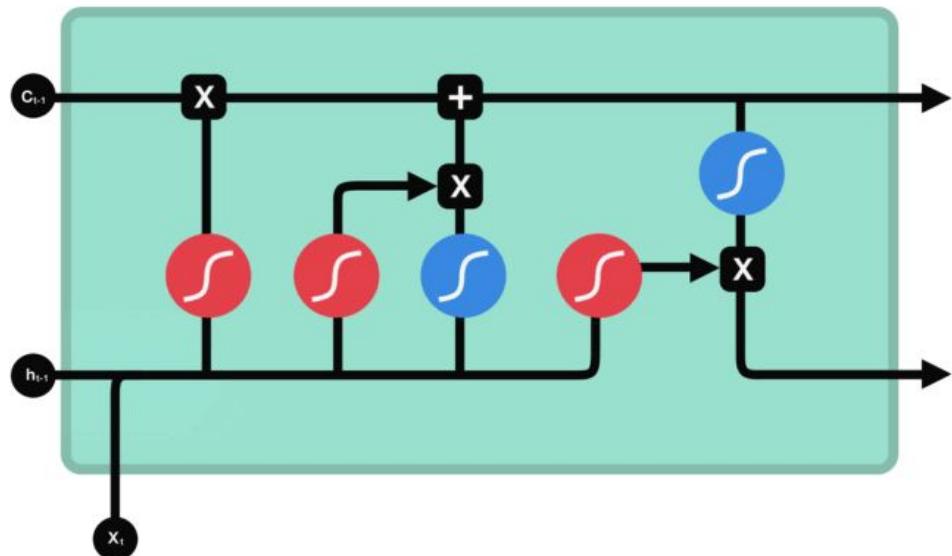

Tanh compresses values between -1 and 1

Sigmoid compresses values between 0 and 1

Useful for updating or forgetting data

Forget Gate

c_{t-1} previous cell state

f_t forget gate output

This gate decides which information should be discarded or kept.

The information from the previous hidden state and the information from the current input are passed through the sigmoid function.

The values are between 0 and 1. Near 0 it forgets and near 1 it keeps

Input Gate

c_{t-1} previous cell state

f_t forget gate output

i_t input gate output

\hat{c}_t candidate

The input gate update the cell state

Previous hidden state and the current input to a sigmoid function.

Hidden state and the current input to the tanh function to compress values between -1 and 1 to help regulate the network. Then you multiply the tanh output by the sigmoid output.

Cell State

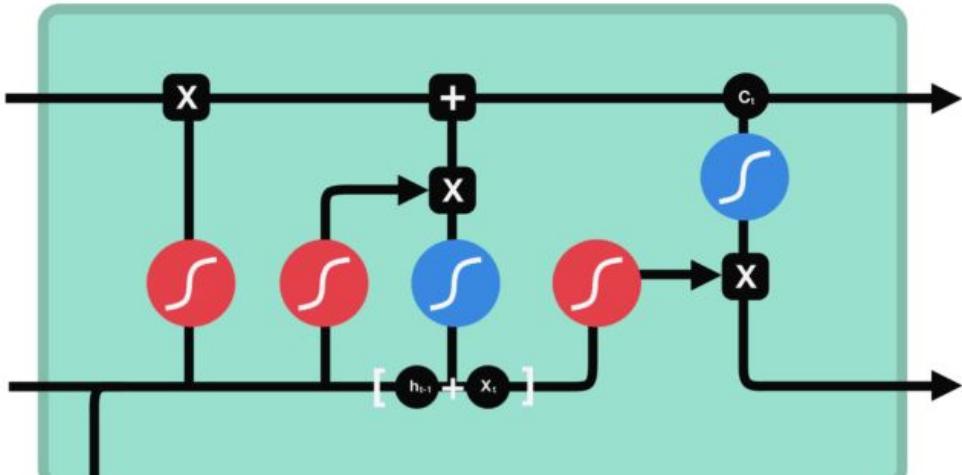

- c_{t-1} previous cell state
- f_t forget gate output
- i_t input gate output
- \tilde{c}_t candidate
- c_t new cell state

The input gate update the cell state
Previous hidden state and the current input to a sigmoid function.
Hidden state and the current input to the tanh function to compress values between -1 and 1 to help regulate the network. Then you multiply the tanh output by the sigmoid output.

$$c_t = f_t * c_{t-1} + i_t * \tilde{c}_t$$

Output Gate

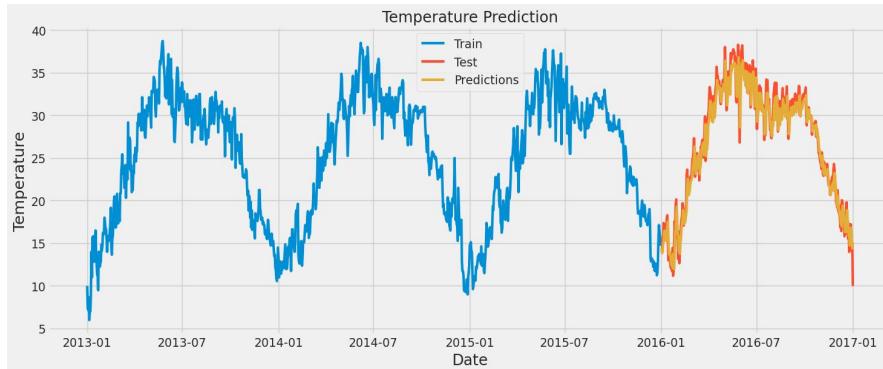

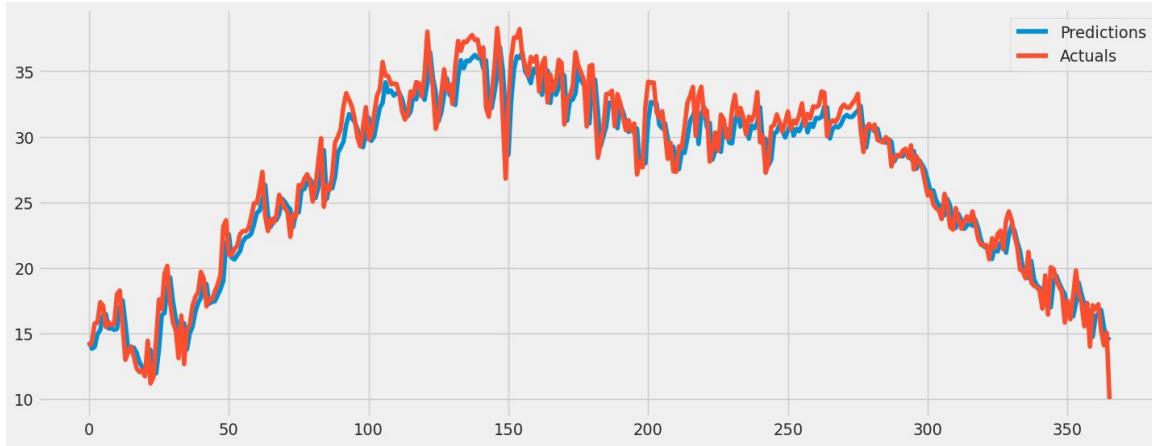

- c_{t-1} previous cell state
- f_t forget gate output
- i_t input gate output
- \tilde{c}_t candidate
- c_t new cell state
- o_t output gate output
- h_t hidden state

The output gate decides what the next hidden state should be.

The hidden state contains information about previous inputs.

We multiply the tanh output by the sigmoid output to decide what information the hidden state should carry.

Abstract

The dominant sequence transduction models are based on complex recurrent or convolutional neural networks that include an encoder and a decoder. The best performing models also connect the encoder and decoder through an attention mechanism. We propose a new simple network architecture, the Transformer, based solely on attention mechanisms, dispensing with recurrence and convolutions entirely. Experiments on two machine translation tasks show these models to be superior in quality while being more parallelizable and requiring significantly less time to train. Our model achieves 28.4 BLEU on the WMT 2014 English-to-German translation task, improving over the existing best results, including ensembles, by over 2 BLEU. On the WMT 2014 English-to-French translation task, our model establishes a new single-model state-of-the-art BLEU score of 41.0 after training for 3.5 days on eight GPUs, a small fraction of the training costs of the best models from the literature.

Attention Is All You Need

1. Identify which parts to attend to
2. Extract the features with high attention

Attention Is All You Need

$$\text{Attention}(\mathbf{q}, \mathcal{D}) \stackrel{\text{def}}{=} \sum_{i=1}^m \alpha(\mathbf{q}, \mathbf{k}_i) \mathbf{v}_i$$
